Choosing a Data Structure

- What type of data needs to be stored?: It might be a possibility that a certain data structure can be the best fit for some kind of data.
- Cost of operations: If we want to minimize the cost for the operations for the most frequently performed operations. For example, we have a simple list on which we have to perform the search operation; then, we can create an array in which elements are stored in sorted order to perform the binary search. The binary search works very fast for the simple list as it divides the search space into half.
- Memory usage: Sometimes, we want a data structure that utilizes less memory.

Tree

- A tree is also one of the data structures that represent hierarchical data.
- Suppose we want to show the employees and their positions in the hierarchical form then it can be represented as shown below:

Tree

- The above tree shows the organization hierarchy of some company. In the above structure, John is the CEO of the company, and John has two direct reports named as Steve and Rohan.
- Steve has three direct reports named Lee, Bob, Ella where Steve is a manager. Bob has two direct reports named Sal and Emma. Emma has two direct reports named Tom and Raj.
- Tom has one direct report named Bill. This particular logical structure is known as a Tree. Its structure is similar to the real tree, so it is named a Tree. In this structure, the root is at the top, and its branches are moving in a downward direction.
- Therefore, we can say that the Tree data structure is an efficient way of storing the data in a hierarchical way.

Tree : Key Points

- A tree data structure is defined as a collection of objects or entities known as nodes that are linked together to represent or simulate hierarchy.
- A tree data structure is a non-linear data structure because it does not store in a sequential manner.
- It is a hierarchical structure as elements in a Tree are arranged in multiple levels.

Tree : Key Points

- In the Tree data structure, the topmost node is known as a root node. Each node contains some data, and data can be of any type.
- In the above tree structure, the node contains the name of the employee, so the type of data would be a string.
- Each node contains some data and the link or reference of other nodes that can be called children.

Tree : Key Points

Introduction to Trees

Tree : Key Points

- Root: The root node is the topmost node in the tree hierarchy. In other words, the root node is the one that doesn't have any parent.
- In the above structure, node numbered 1 is the root node of the tree. If a node is directly linked to some other node, it would be called a parent-child relationship.
- Child node: If the node is a descendant of any node, then the node is known as a child node.
- Parent: If the node contains any sub-node, then that node is said to be the parent of that sub-node.

Tree : Key Points

- Sibling: The nodes that have the same parent are known as siblings.
- Leaf Node:- The node of the tree, which doesn't have any child node, is called a leaf node. A leaf node is the bottom-most node of the tree. There can be any number of leaf nodes present in a general tree. Leaf nodes can also be called external nodes.
- Internal nodes: A node has atleast one child node known as an internal

Tree : Key Points

- Ancestor node:- An ancestor of a node is any predecessor node on a path from the root to that node.
- The root node doesn't have any ancestors. In the tree shown in the above image, nodes 1, 2, and 5 are the ancestors of node 10.
- Descendant: The immediate successor of the given node is known as a descendant of a node. In the above figure, 10 is the descendant of node 5.

Tree : Properties

- Recursive data structure:
 - The tree is also known as a recursive data structure. A tree can be defined as recursively because the distinguished node in a tree data structure is known as a root node.
 - The root node of the tree contains a link to all the roots of its subtrees. The left subtree is shown in the yellow color in the below figure, and the right subtree is shown in the red color.
 - The left subtree can be further split into subtrees shown in three different colors. Recursion means reducing something in a self-similar manner.

Tree : Properties

Tree : Properties

- Number of edges: If there are n nodes, then there would $n-1$ edges. Each arrow in the structure represents the link or path. Each node, except the root node, will have at least one incoming link known as an edge. There would be one link for the parent-child relationship.
- Depth of node x : The depth of node x can be defined as the length of the path from the root to the node x . One edge contributes one-unit length in the path. So, the depth of node x can also be defined as the number of edges between the root node and the node x . The root node has 0 depth.
- Height of node x : The height of node x can be defined as the longest path from the node x to the leaf node.

Tree: Implementation

Tree: Implementation

- struct node
{
 int data;
 struct node *left;
 struct node *right;
}
- The above structure can only be defined for the binary trees because the binary tree can have utmost two children, and generic trees can have more than two children.
- The structure of the node for generic trees would be different as compared to the binary tree.

Tree: Application

- Storing naturally hierarchical data: Trees are used to store the data in the hierarchical structure. For example, the file system. The file system stored on the disc drive, the file and folder are in the form of the naturally hierarchical data and stored in the form of trees.
- Organize data: It is used to organize data for efficient insertion, deletion and searching. For example, a binary tree has a $\log N$ time for searching an element.
- Trie: It is a special kind of tree that is used to store the dictionary. It is a fast and efficient way for dynamic spell checking.

Tree: Application

- Heap: It is also a tree data structure implemented using arrays. It is used to implement priority queues.
- B-Tree and B+Tree: B-Tree and B+Tree are the tree data structures used to implement indexing in databases.
- Routing table: The tree data structure is also used to store the data in routing tables in the routers.

Type: General Tree

- The general tree is one of the types of tree data structure. In the general tree, a node can have either 0 or maximum n number of nodes.
- There is no restriction imposed on the degree of the node (the number of nodes that a node can contain). The topmost node in a general tree is known as a root node. The children of the parent node are known as subtrees.

Type: Binary Tree

- Here, binary name itself suggests two numbers, i.e., 0 and 1. In a binary tree, each node in a tree can have utmost two child nodes. Here, utmost means whether the node has 0 nodes, 1 node or 2 nodes.

Type: Full Binary Tree

- A full binary tree can be defined as a binary tree in which all the nodes have 0 or two children.
- In other words, the full binary tree can be defined as a binary tree in which all the nodes have two children except the leaf nodes.

Type: Complete Binary Tree

- A complete binary tree is a binary tree in which all levels are completely filled, except possibly the last level, which is filled from left to right.
- The complete binary tree has the following properties:
 - All levels except the last level are completely filled.
 - The last level is filled from left to right.
 - All leaf nodes are at the same depth.

Type: Complete Binary Tree

Type: Binary Search Tree

- Binary search tree is a non-linear data structure in which one node is connected to n number of nodes. It is a node-based data structure.
- A node can be represented in a binary search tree with three fields, i.e., data part, left-child, and right-child. A node can be connected to the utmost two child nodes in a binary search tree, so the node contains two pointers (left child and right child pointer).
- Every node in the left subtree must contain a value less than the value of the root node, and the value of each node in the right subtree must be bigger than the value of the root node.

Type: AVL Tree

- It is one of the types of the binary tree, or we can say that it is a variant of the binary search tree. AVL tree satisfies the property of the binary tree as well as of the binary search tree.
- It is a self-balancing binary search tree that was invented by Adelson Velsky Lindas. Here, self-balancing means that balancing the heights of left subtree and right subtree.
- This balancing is measured in terms of the balancing factor.

Type: AVL Tree

AVL Tree

Type: AVL Tree

- We can consider a tree as an AVL tree if the tree obeys the binary search tree as well as a balancing factor.
- The balancing factor can be defined as the difference between the height of the left subtree and the height of the right subtree.
- The balancing factor's value must be either 0, -1, or 1; therefore, each node in the AVL tree should have the value of the balancing factor either as 0, -1, or 1.

Tree Traversal: DFS

- The term 'tree traversal' means traversing or visiting each node of a tree.
- The algorithm begins at the root node and then it explores each branch before backtracking. It is implemented using stacks.
- Often while writing the code, we use recursion stacks to backtrack.
- By using recursion we are able to take advantage of the fact that left and right subtrees are also trees and share the same properties.

Tree Traversal

- There is a single way to traverse the linear data structure such as linked list, queue, and stack. Whereas, there are multiple ways to traverse a tree that are listed as follows -
 - Preorder traversal
 - Inorder traversal
 - Postorder traversal

Preorder Traversal

- This technique follows the 'root left right' policy. It means that, first root node is visited after that the left subtree is traversed recursively, and finally, right subtree is recursively traversed.
- As the root node is traversed before (or pre) the left and right subtree, it is called preorder traversal.
- So, in a preorder traversal, each node is visited before both of its subtrees.

Preorder Traversal

- The applications of preorder traversal include -
 - It is used to create a copy of the tree.
 - It can also be used to get the prefix expression of an expression tree.
- Algorithm
 - Until all nodes of the tree are not visited
 - Step 1 - Visit the root node
 - Step 2 - Traverse the left subtree recursively.
 - Step 3 - Traverse the right subtree recursively.

Preorder Traversal

$A \rightarrow B \rightarrow D \rightarrow E \rightarrow C \rightarrow F \rightarrow G$

Postorder Traversal

- This technique follows the 'left-right root' policy. It means that the first left subtree of the root node is traversed, after that recursively traverses the right subtree, and finally, the root node is traversed.
- As the root node is traversed after (or post) the left and right subtree, it is called postorder traversal.
- So, in a postorder traversal, each node is visited after both of its subtrees.

Postorder Traversal

- The applications of postorder traversal include -
 - It is used to delete the tree.
 - It can also be used to get the postfix expression of an expression tree.
- Algorithm
 - Until all nodes of the tree are not visited
 - Step 1 - Traverse the left subtree recursively.
 - Step 2 - Traverse the right subtree recursively.
 - Step 3 - Visit the root node.

Postorder Traversal

$D \rightarrow E \rightarrow B \rightarrow F \rightarrow G \rightarrow C \rightarrow A$

Inorder Traversal

- This technique follows the 'left root right' policy. It means that first left subtree is visited after that root node is traversed, and finally, the right subtree is traversed.
- As the root node is traversed between the left and right subtree, it is named inorder traversal.
- So, in the inorder traversal, each node is visited in between of its subtrees.

Inorder Traversal

- The applications of Inorder traversal includes -
 - It is used to get the BST nodes in increasing order.
 - It can also be used to get the prefix expression of an expression tree.
- Algorithm
 - Until all nodes of the tree are not visited
 - Step 1 - Traverse the left subtree recursively.
 - Step 2 - Visit the root node.
 - Step 3 - Traverse the right subtree recursively.

Inorder Traversal

$D \rightarrow B \rightarrow E \rightarrow A \rightarrow F \rightarrow C \rightarrow G$

Complexities of Tree Traversal

- The time complexity of tree traversal techniques discussed above is $O(n)$, where 'n' is the size of binary tree.
- Whereas the space complexity of tree traversal techniques discussed above is $O(1)$ if we do not consider the stack size for function calls.
- Otherwise, the space complexity of these techniques is $O(h)$, where 'h' is the tree's height.

Breadth First Search

- This algorithm also begins at the root node and then visits all nodes level by level.
- That means after the root, it traverses all the direct children of the root.
- After all direct children of the root are traversed, it moves to their children and so on.

BFS vs. DFS

BFS

A B C D E F

DFS

A D F C E B
