

1 2 3 4 5  $\Rightarrow$ 

0	1	2	3	4	
1	2	3	4	5	...

count = 5

## Dynamic Memory Allocation

int n;  
std::cin >> n;

malloc() ↓ number of bytes to allocate  
↑ allocates memory in heap.  
free()  
#include <stdlib.h>

int \* p = (int \*) malloc (n \* sizeof(int));

Release the memory that was allocated by malloc.

`free(pi);`

---

`void *` `malloc (int size);`

`void *`  $\Rightarrow$  word pointer  $\rightarrow$  stores an address

↙  
Can not do  
any pointer  
arithmetic

↓  
Can not dereference a  
void pointer

```
int * pi = (int *) malloc ( ... );  
if ( pi == NULL ) {  
    std::cout << "failed to allocate mem";  
    return 0;  
}
```

free (pi);

↓  
return address  
if memory was  
allocated else  
returns NULL

creates a user defined type  $\Leftarrow$  struct  $\rightarrow$

we want to combine multiple value together that are related to each other.

$\left. \begin{array}{l} \text{int rollNo;} \\ \text{float marks;} \end{array} \right\}$  Info of a student

struct Student Info {  
    int rollNo;  
    float marks;  
};

$\rightarrow$  type name

$\rightarrow$  fields

struct Student Info s1;

s1.rollNo = 5;

s1.marks = 10;

struct Student Info s2;

s2 = s1; ✓

~~if (s1 == s2) {~~  
~~}~~

class → keyword using which  
we define a user defined  
type.

OOP

↙ ↘ data abstraction  
↓  
data hiding.

data  
encapsulation

├ data  
└ operation

are combined  
in a single entity. ⇒ class

```

int main() {
    BigInt i = 10;
    int j = 10;
}

```

class → BigInt  
 object → i  
 variable → j

```

i = i + j;
if (i == 100) {
    :
}
i = i * 10;
j = j * 10;

```

```

class BigInt {
    int num;
}
int main() {
    BigInt i;
    i.num = 10;
    :
    :
}

```

member variable → num  
 private member → num (marked with a red X)

private      public      protected

→ access  
specifiers to  
class members.

```
class BigInt {
```

```
    public:
```

```
        int num;
```

```
}
```

```
int main() {
```

```
    BigInt i;
```

```
    i.num = 10;
```

```
}
```

```
class BigInt {
```

```
    int num;
```

member  
variable

```
public:
```

```
    void setNum (int n) {
```

```
        num = n;
```

```
    }
```

```
    int getNum () {
```

```
        return num;
```

```
    }
```

```
}
```

member  
function

int main() {

BigInt i;

~~i.num = 10;~~ → as num is private

i.setNum(10); ✓

BigInt j = 10;

num is private

Parameterised  
Constructor

Gets called when we create  
an object without initializing.

Constructor that do not  
take any argument.

```
class Big Int {  
    int num;
```

default  
constructor

gets called when  
an object of  
class is  
created.

public:

```
    Big Int ( ) {  
    }
```

← constructor

name of constructor is same  
as name of class.

do not  
have  
return type  
not even void

```
    Big Int (int n) {
```

← Parameterised  
constructor

```
}
```

```
    num = n;
```

→ assignment

Not  
the  
correct  
way.

```
BigInt ( int n) { num (n) }  
    num = n;  
    ↓  
    this → num = n;
```

member  
initializer list

```
BigInt ( int n, int m) : num (n + m)  
{  
}
```

```
int main() {  
    BigInt R( 10, 20);  
}
```

Destructor

→ member function that gets called when an object is destroyed (memory is getting freed).

↓ + class Name

```
~BigInt () {  
    }  
}
```

↑  
destructor never  
receive argument

int main() {

BigInt i(10);

BigInt j(20);

if (i == j)  $\Rightarrow$  `i.operator==(j)`

std::cout << "eq";

else  
std::cout << "neg";

i.Read();      j.Write();

Operator function → a function implemented to define behaviour of a built in operator for user defined type.

Operator overloading ⇒

⇓

implement a member function (it can also be a non-member) with name as operator. → Rgy wood

```
class BigInt {  
    :
```

```
public:
```

```
    bool operator == (BigInt obj2) {
```

```
        if (num == obj2.num)
```

```
            return true;
```

this → num

```
        return false;
```

```
}
```

```
void Read() {
```

```
    std::cin >> num;
```

```
}  
    void write() {  
        std::cout << num;  
    }  
}
```

cout → object of class ostream

cin → object of class istream

iostream.h  
↓  
all identifiers  
are declared in global scope

iostream  
every thing declared  
in iostream.h  
but in a  
namespace-std.

```
namespace N1 {
```

```
    int a = 10;
```

```
    void f1() {
```

```
        :
```

```
    }
```

```
}
```

```
namespace N2 {
```

```
    int a = 20;
```

```
}
```

```
int main() {
```

```
    N1::a = 5;
```

↑  
Scope resolution  
operator

```
    N2::a = 13;
```

namespace N1 {

int a = 10;

namespace N2 {

int a = 20;

}

int main() {

N1::a = 5;

N1::N2::a = 1;

}

int a = 10;

int main() {

int a = 5;

std::cout << a;

```
std::cout << a;
```

global namespace

```
}
```

```
#include <iostream>
using namespace std;
int main() {
```

⇒

add all identifiers  
of std namespace  
to global scope

```
std::cout << "...";
:
:
```

```
}
```
